Hybrid Finite Element-Finite Volume Algorithm for Solving Transient Multi-Scale Fluid-Structure Interaction during Operation of a Hydraulic Seal

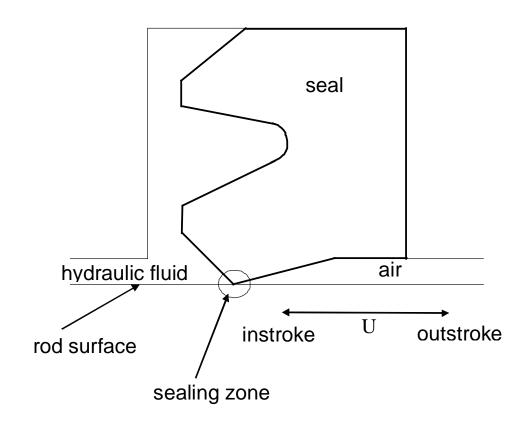

Azam Thatte Richard Salant Georgia Institute of Technology

Background

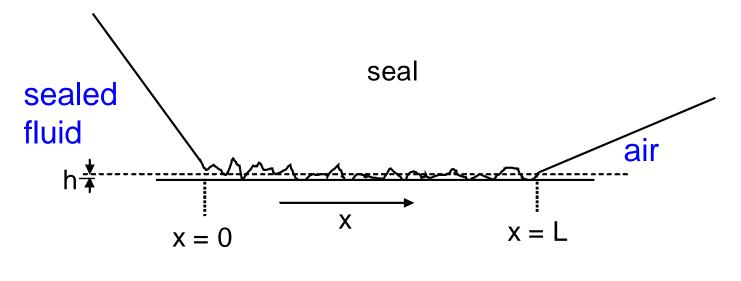

Rod seals : among the most critical elements in hydraulic equipments – prevent hydraulic fluid from entering the environment.

Problem Decomposition & Hybrid Framework

Multi-scale FSI model consists of :

- Macro-scale structural mechanics for the seal deformations (F.E.) .
- Micro-scale fluid mechanics of the lubricating film in the sealing zone (F.V.) .
- Micro-scale statistical contact mechanics of the contacting asperities on the seal lip.
- Micro-scale elastic deformation mechanics of the sealing zone (F.E) .
- Macro-scale elastic contact mechanics at the seal-rod interface (F.E) .

A single hybrid finite element – finite volume framework, incorporating all these models, will solve these highly coupled nonlinear multiphysics equations simultaneously.

Macro-Scale Deformation Mechanics

- Macro-scale deformation mechanics for the seal mounted between the housing and rod, under pressurized conditions.
- Solved using an in-house MATLAB code coupled with COMSOL's finite element code.
- The seal is modeled as a nearly incompressible, linear, elastic and isotropic material with small deformation theory. The principle of virtual work for the axisymmetric system reads,

$$2\pi \int_{A} r \begin{pmatrix} -\varepsilon_{rtest} \sigma_{r} - \varepsilon_{\theta test} \sigma_{\theta} - \varepsilon_{ztest} \sigma_{z} \\ -2\varepsilon_{rztest} \tau_{rz} + r.uor_{test} F_{r} + w_{test} F_{z} \end{pmatrix} dA + 2\pi \int_{l} r (r.uor_{test} F_{r} + w_{test} F_{z}) dl \\ + (r.uor_{test} F_{r} + w_{test} F_{z}) = 0$$

- Mixed formulation is used to model near incompressibility.
- Negative mean stress is added as a new dependent variable and the stress tensor is decomposed into a deviatoric part and a mean part.

$$\boldsymbol{\sigma} = \boldsymbol{\sigma}_d - \boldsymbol{m}\,\tilde{\boldsymbol{p}}$$
$$\tilde{\boldsymbol{p}} = \tilde{\boldsymbol{p}}_0 - \boldsymbol{K}\,\mathbf{m}\boldsymbol{\varepsilon}^T\left(\boldsymbol{\varepsilon} - \boldsymbol{0}\right)$$

Micro-Scale Fluid Mechanics

- The micro-scale fluid mechanics in the sealing zone is governed by the transient Reynolds equation.
- Model takes into account cavitation and squeeze film effects.

$$\frac{\partial}{\partial \hat{z}} \left(\phi_{xx} H^3 e^{-\hat{\alpha}F\phi} \frac{\partial}{\partial \hat{z}} (F\phi) \right) = 6\zeta \frac{\partial}{\partial \hat{z}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} \left\{ H_T + \phi_{s.c.x} \right\} \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} H_T \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(\left\{ 1 + \left(1 - F\right)\phi \right\} \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(1 + \left(1 - F\right)\phi \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(1 + \left(1 + F\right)\phi \right) + 1 \varepsilon 2 \frac{\partial}{\partial \hat{t}} \left(1 + \left(1 + F\right)$$

 ϕ_{xx} , $\phi_{s.c.x}$: Flow factors to account for surface roughness effects of seal lip

In the liquid region:

$$\phi \ge 0$$
, $F = 1$ and $P = \phi$

In the cavitated region:

$$\phi < 0, F = 0, P = 0 \text{ and } \hat{\rho} = 1 + \phi$$

Boundary conditions :

$$P = P_{sealed}$$
 at $\hat{z} = 0$
 $P = 1$ at $\hat{z} = 1$

Micro-Scale Fluid Mechanics continued...

• The average truncated film thickness is given by,

$$H_T = \int_{-H}^{\infty} (H + \delta) f(\delta) d\delta$$

• Gaussian distribution of asperities is assumed which yields

$$H_T = \frac{H}{2} + \frac{H}{2} \operatorname{erf}\left[\frac{H}{\sqrt{2}}\right] + \frac{1}{\sqrt{2\pi}} e^{-H^2/2}$$

- Fluid equations solved for ϕ and F at each time step numerically with a finite volume formulation.
- Set of linear algebraic equations is solved using the tri-diagonal matrix algorithm (TDMA).
- Time integration is carried out using a fully implicit method giving an unconditional numerical stability to the procedure.
- Solution yields the fluid pressure distribution and location of cavitation zones at each time step.

Micro-Scale Statistical Contact Mechanics

- Significant asperity contact may occur during mixed lubrication.
- Necessity to add an micro-scale asperity contact pressure to the hydrodynamic pressure in computing radial seal deformations and local film thickness.
- Assuming Gaussian distribution of asperity heights, the micro-scale contact pressure is given by,

$$P_{c} = \frac{4}{3} \frac{1}{\left(1 - \nu^{2}\right)} \hat{\sigma}^{3/2} \frac{1}{\sqrt{2\pi}} \int_{H}^{\infty} \left(\delta - H\right)^{3/2} e^{-\delta^{2}/2} d\delta$$

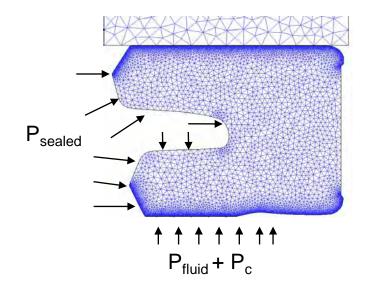

• Integral calculated using "Adaptive Gauss-Kronrod" quadrature.

Micro-Scale Deformation Mechanics

- Needed to get micro-scale film thickness distribution at each time step.
- Radial deformations of sealing element under combined action of sealed pressure, fluid pressure and contact pressure.
- In discretized form with *n* axial nodes along the sealing zone, the film thickness at the i th node can be expressed as,

$$H_i = H_d + \left(H_{def}\right)_i$$

- $(H_{def})_i$: Obtained from F.E. calculations after applying a net pressure of $(P_t P_{dc})$ over the contact zone.
- H_d : Thickness that a hypothetical film would occupy under dry contact conditions.

Micro-Scale Deformation Mechanics continued..

- H_d Computed by equating dry contact pressure P_{dc} from the macro-scale F.E. analysis with the statistical micro-scale contact pressure P_c .
- Using a curve fit method to invert equation for P_c yields,

$$H_{d} = a + b \cdot \log(x) + c \cdot (\log(x))^{2} + d \cdot (\log(x))^{3} + e \cdot (\log(x))^{4} + f \cdot (\log(x))^{5}$$

x = -
$$\log_{10} |I|$$

 $I = \frac{P_{dc}}{\frac{4}{3(1-\nu^2)}\hat{\sigma}^{3/2}}$

Macro-Scale Contact Mechanics

- To obtain *P_{dc}*, the macro-scale F.E. contact mechanics is solved at the seal-rod interface and seal-housing interface.
- Augmented Lagrangian method used. Augmentation component introduced for dry contact pressure.
- For each slave point, a corresponding master point is searched in the direction perpendicular to the slave boundary.
- The contact interaction gives the following contribution to the weak form on the slave boundary

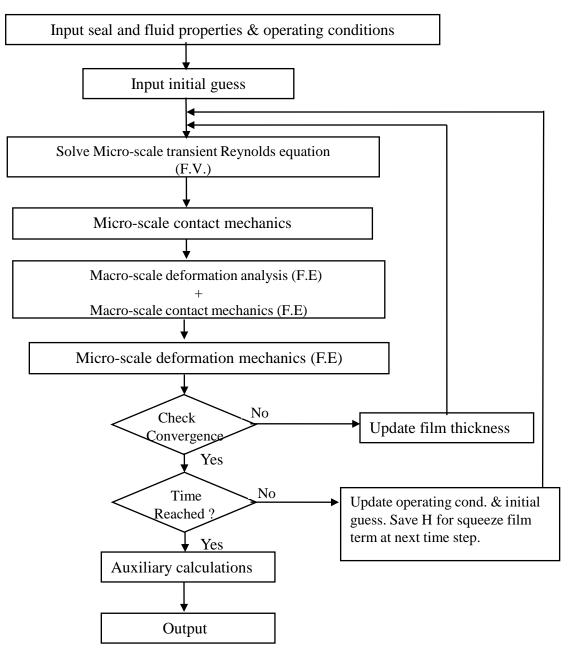

$$\int_{slave} \left[\left(P_{dc,p} \delta \lambda + P_{dt,p} \cdot \Re(\mathbf{F}_D) \delta(\Re(X)) \right) + \left(C_1 \delta P_{dc} + C_2 \cdot \delta P_{dt} \right) \right] dA$$

• The augmented dry contact pressure defined on the slave boundary is given by :

 $P_{dc,p} = P_{dc} - \varepsilon_n \lambda \quad ; \ \lambda \le 0$ $\varepsilon_n : \text{ normal penalty factor} \quad \lambda : \text{gap variable}$

Flow Chart for Hybrid Algorithm

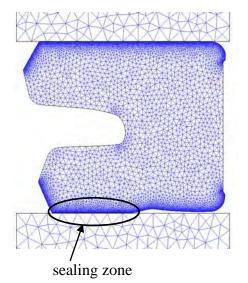

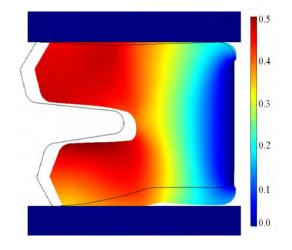

Base Parameters

| Elastic modulus | 43 x 10 ⁶ Pa |
|--------------------------------|--|
| Poisson's ratio | 0.49 |
| Sealed pressure | 6.90 MPa |
| Rod diameter | 88.9 mm |
| Stroke | 1.93 m |
| Reference viscosity | 0.043 Pa-s |
| Pressure-viscosity coefficient | 20 x 10 ⁻⁹ Pa ⁻¹ |
| Asperity radius | 1 μm |
| Asperity density | 10^{14} m^{-2} |
| Asperity contact friction | 0.25 |
| coefficient | |

Conclusions

- Hybrid framework of finite element finite volume solution algorithms for solving highly coupled, nonlinear, multiscale fluid-structure interaction is developed.
- Hybrid method facilitated an *online* calculation of micro-scale deformations necessary to model the transient seal response.
- Transient FSI solution revealed the history of a reciprocating seal's behavior over a cycle.
- Solution confirmed the presence of a "critical seal roughness" needed to prevent the leakage.
- Solution showed that thinner films during the outstroke than during the instroke, and cavitation during the outstroke, are characteristics of a non-leaking seal.
- It also provided insight into why the behaviors during outstroke and instroke differ.
