The Non Linear Behaviour of the Microplane Model in COMSOL

A. Frigerio

COMSOL Conference 2012 - Milan (Italy)

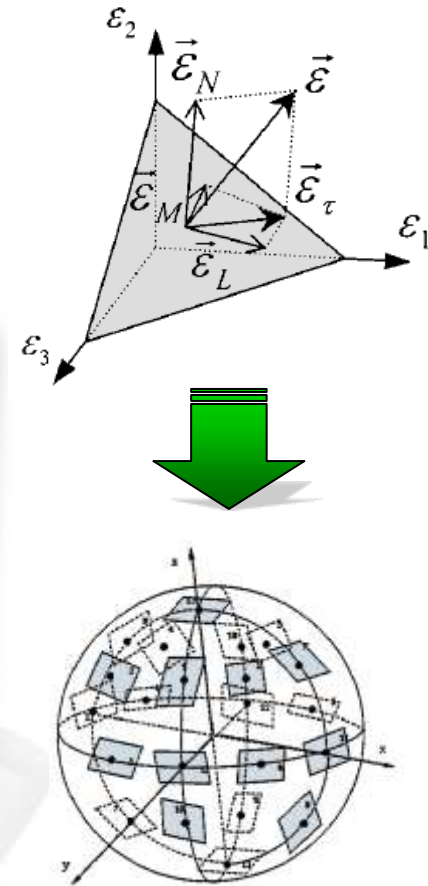

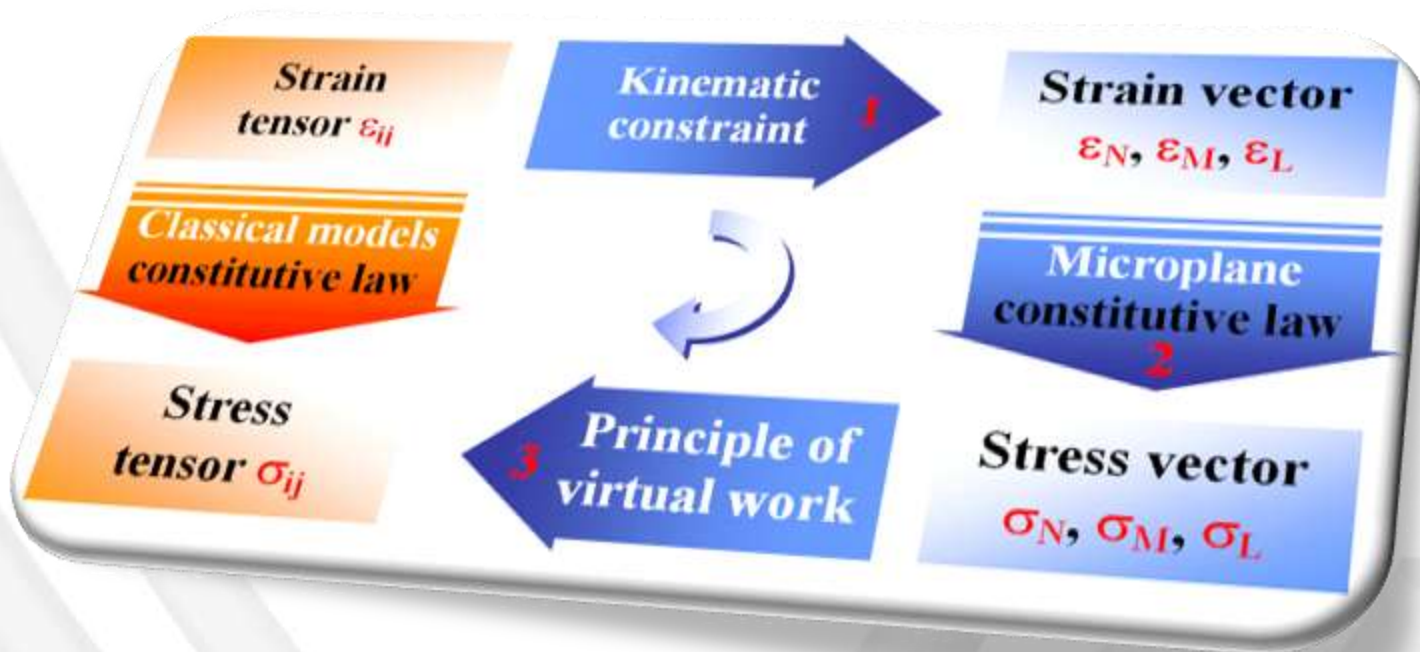

- Aims of the work
- The Microplane Model
 - A few hints on the main theory aspects
 - The non-linear behaviour
- Implementation process of the non-linear behaviour within COMSOL
- Conclusions

- Why the need to have another constitutive model for concrete?
 - Classical constitutive models are able to properly simulate *only a few specific characteristic* of concrete
 - The Microplane Model is a promising alternative approach able to simulate *the overall behaviour* of concrete

The Microplane Model: theory

- *Logical scheme* of the linear elastic behaviour of the **Microplane Model** compared with that of **classical approaches**

- The *non-linear behaviour* is based on the definition of **stress-strain boundaries** at the microplane level:
 - Within the domain these boundaries mark out the material response is incremental elastic
 - Movements along these boundaries are permitted only if strain and stress increments have the same sign, otherwise elastic unloading occurs

The Microplane model: the non-linear behaviour (2/2)

- Damage can be modelled reducing progressively the elastic moduli of the incremental laws within the elastic domain
- The boundaries are characterized by **17 constant** material parameters and **4 free** parameters

$c_1, c_2 \dots c_{17}$ & $k_1, k_2 \dots k_4$

- The constant parameters should be kept fixed for all types of concrete
- The free parameters should be identified fitting test data

Tensile normal boundary

$$\sigma_N = \sigma_V + \sigma_D$$

Volumetric boundaries

$$\dot{\sigma}_V = E_V \dot{\epsilon}_V$$

Deviatoric boundaries

$$\dot{\sigma}_D = E_D \dot{\epsilon}_D$$

Frictional yield boundary

$$\sigma_T = \sqrt{\sigma_M^2 + \sigma_L^2}$$

$$\dot{\sigma}_M = E_M \dot{\epsilon}_M \quad \dot{\sigma}_L = E_L \dot{\epsilon}_L$$

Implementation within COMSOL

SigmaN

The screenshot shows the COMSOL Multiphysics interface for a model named 'cubettoMP28_NonLin_Compressione_20120921.mph'. The 'Model Builder' window is open, showing a tree view of the model structure. The 'Model 1 (mod1)' node is selected, and the 'Definitions' sub-node is expanded, showing a list of variables including 'sigmaN'. The 'Variables' table is displayed on the right, showing the following data:

| Name | Expression |
|--------|---|
| sNb01 | $Young * k1 * c1 * \exp(-\max(eN01 \text{int} - c1 * c2 * k1, 0.)) / (k1 * c3 + \max(-c4 * (sV01 / EV), 0.))$ |
| sDb01p | $Young * k1 * c5 / (1 + (\max(eD01 \text{int} - c5 * c6 * k1, 0.)) / (k1 * c17 * c7))^2$ |
| sDb01n | $-Young * k1 * c8 / (1 + (\max(-eD01 \text{int} - c8 * c9 * k1, 0.)) / (k1 * c7))^2$ |
| sDc01 | $(sD01 >= 0) * \min(sDb01p, sD01) + (sD01 < 0) * \max(sDb01n, sD01)$ |
| sVb01p | $Young * k1 * c13 / (1 + (c14 / k1) * \max(eV01 \text{int} - k1 * c13, 0.))^2$ |
| sVb01n | $-Young * k1 * k3 * \exp(-eV01 \text{int} / (k1 * k4))$ |
| sVc01 | $(sV01 >= 0) * \min(sVb01p, sV01) + (sV01 < 0) * \max(sVb01n, sV01)$ |
| sN01 | $\min(sNb01, sVc01 + sDc01)$ |
| sNT01 | $ET * k1 * c11 / (1 + c12 * \max(eV01 \text{int}, 0.))$ |
| sTb01 | $ET * k1 * k2 * c10 * \max(-sN01 + sNT01, 0.)) / (ET * k1 * k2 + c10 * \max(-sN01 + sNT01, 0.))$ |
| sT01 | $(sM01^2 + sL01^2)^{0.5}$ |
| sMc01 | $\text{if}(sT01 > sTb01, sM01 * sTb01 / sT01, sM01)$ |
| sLc01 | $\text{if}(sT01 > sTb01, sL01 * sTb01 / sT01, sL01)$ |

Tensile normal boundary

$$\sigma_N^b = E k_1 c_1 \exp\left(-\frac{\langle \varepsilon_N - c_1 c_2 k_1 \rangle}{k_1 c_3 + \langle -c_4 (\sigma_V / E_V) \rangle}\right)$$

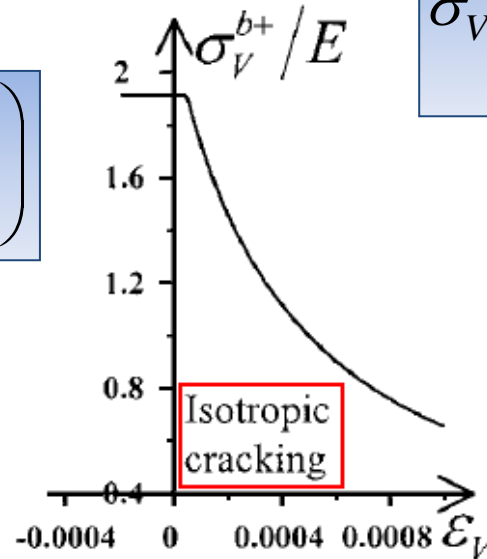

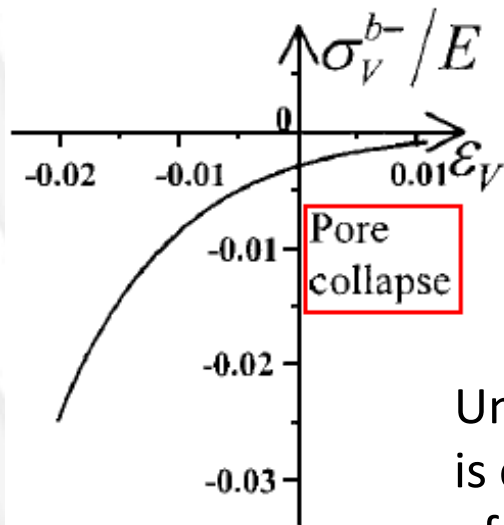

- The initial descending part describes the tensile cracking parallel to the microplane
- The tail defines the frictional pullout of fragments bridging the crack surfaces

$$s_{Nbkk} = \text{Young} * k_1 * c_1 * \exp(-\max(\varepsilon_N k_1 c_1 - c_1 * c_2 * k_1, 0.) / (k_1 * c_3 + \max(-c_4 * (\sigma_V c_k / E_V), 0.)))$$

$$s_{Nkk} = \min(s_{Nbkk}, s_{Vckk} + s_{Dckk})$$

Volumetric boundaries

$$\sigma_V^b = -Ek_1k_3 \exp\left(-\frac{\varepsilon_V}{k_1k_4}\right)$$

$$\sigma_V^b = \frac{Ek_1c_{13}}{\left[1 + (c_{14}/k_1)\langle\varepsilon_V - k_1c_{13}\rangle\right]^2}$$

A tensile volumetric boundary is needed to prevent unreasonable lateral strains in post peak softening under uniaxial, unconfined, tension

Under hydrostatic pressure a progressive stronger hardening is considered to primarily represent the collapse and closure of pores

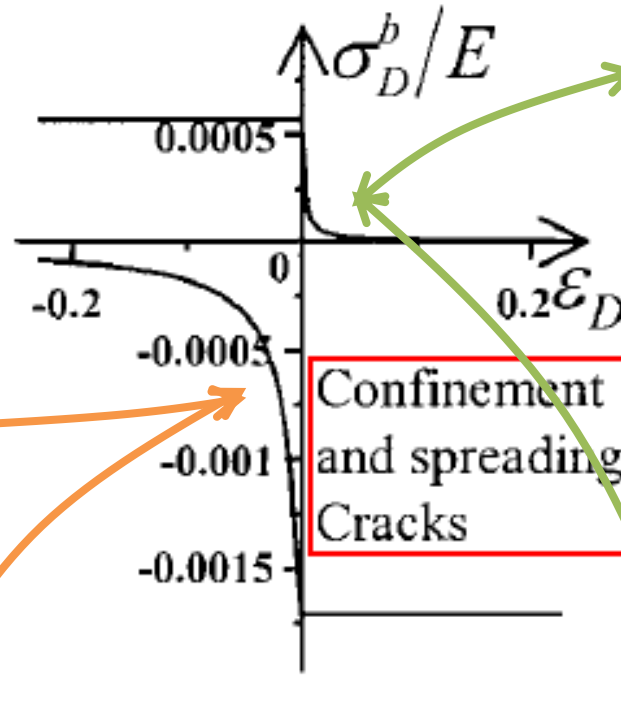

$$sVbkkn = -\text{Young} * k_1 * k_3 * \exp(-\varepsilon_V / (k_1 * k_4))$$

$$sVbkkp = \text{Young} * k_1 * c_{13} / (1 + (c_{14}/k_1) * \max(\varepsilon_V - k_1 * c_{13}, 0))^2$$

$$sVckk = (sVkk \geq 0) * \min(sVbkkp, sVkk) + (sVkk < 0) * \max(sVbkkn, sVkk)$$

Deviatoric boundaries

The compressive deviatoric curve controls the axial crushing strain of concrete in compression when lateral confinement is too weak to prevent crushing

The tensile deviatoric curve:

- simulates transverse crack opening of axial distributed cracks in compression
- controls the volumetric expansion and lateral strains in unconfined compression tests

$$\sigma_D^b = - \frac{Ek_1c_8}{1 + \left(\langle -\varepsilon_D - c_8c_9k_1 \rangle / k_1c_7 \right)^2}$$

$$\sigma_D^b = \frac{Ek_1c_5}{1 + \left(\langle \varepsilon_D - c_5c_6k_1 \rangle / k_1c_{17}c_7 \right)^2}$$

$$sDbkkn = -\text{Young} * k_1 * c_8 / (1 + (\max(-\varepsilon_D k_1 c_8 - c_8 * c_9 * k_1, 0) / (k_1 * c_7)))^2$$

$$sDbkcp = \text{Young} * k_1 * c_5 / (1 + (\max(\varepsilon_D k_1 c_5 - c_5 * c_6 * k_1, 0) / (k_1 * c_{17} * c_7)))^2$$

$$sDckk = (sDkk \geq 0) * \min(sDbkcp, sDkk) + (sDkk < 0) * \max(sDbkkn, sDkk)$$

Frictional yield boundary

$$\lim_{\sigma_N \rightarrow -\infty} \sigma_T = E_T k_1 k_2$$

At very high confining pressures, concrete becomes a plastic but frictionless material

$$\left[\frac{d\sigma_T}{d\sigma_N} \right]_{\sigma_N=0} = -c_{10}$$

For small volumetric strain, a finite cohesive stress, which decreases to zero with increasing volumetric strain, is provided

$$\sigma_T^b = \frac{E_T k_1 k_2 c_{10} \langle -\sigma_N + \sigma_N^0 \rangle}{E_T k_1 k_2 + c_{10} \langle -\sigma_N + \sigma_N^0 \rangle}$$

$$\sigma_N^0 = \frac{E_T k_1 c_{11}}{1 + c_{12} \langle \epsilon_V \rangle}$$

$$sNTkk = ET*k1*c11/(1+c12*max(eVkkint,0.))$$

$$sTbkk = ET*k1*k2*c10*max(-sNkk+sNTkk,0.)/(ET*k1*k2+c10*max(-sNkk+sNTkk,0.))$$

$$sTkk = (sMkk^2+sLkk^2)^0.5$$

$$sMckk = \text{if}(sTkk>sTbkk,sMkk*sTbkk/sTkk,sMkk)$$

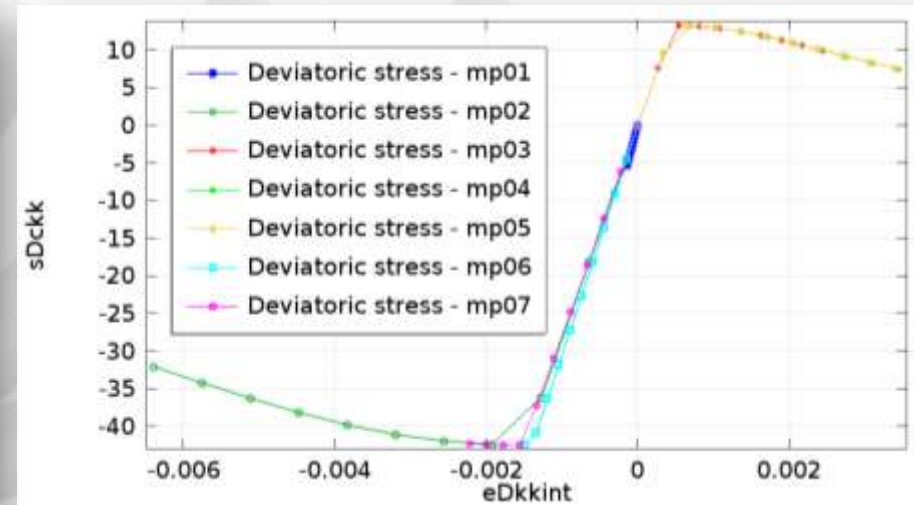

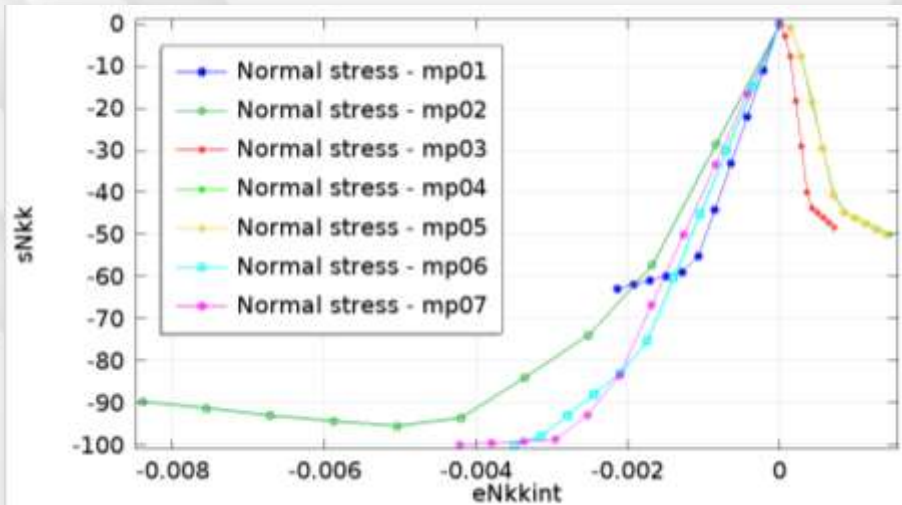

$$sLckk = \text{if}(sTkk>sTbkk,sLkk*sTbkk/sTkk,sLkk)$$

Validation of the model

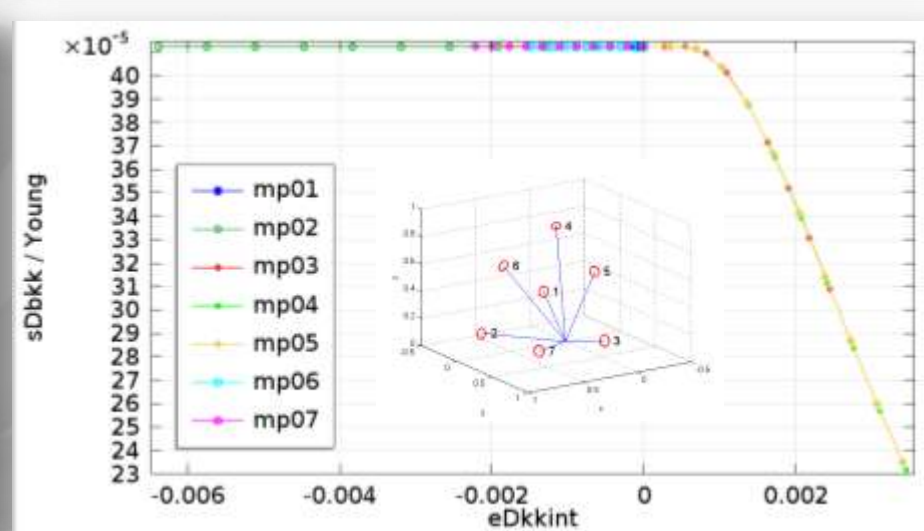

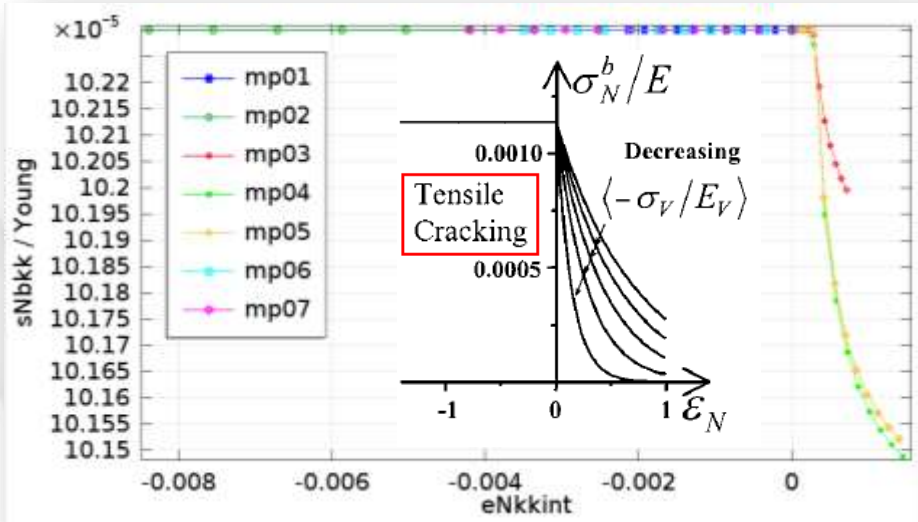

Compression test

Results in terms of stress

Non-linear boundaries check during a compression/traction test

Validation of the model

Conclusions

- An accurate identification of the free material parameters and the constant ones is needed
- Applying the Microplane Model to simulate the concrete behaviour of large structures, such as dams, presenting an evident crack pattern

The end

**Thank you
for your attention**
